

Backward Induction

Game Theory Course: Jackson, Leyton-Brown & Shoham

Computing Subgame Perfect Equilibria

Idea: Identify the equilibria in the bottom-most trees, and adopt

these as one moves up the tree

```
 \begin{array}{l} \mbox{function BACKWARDINDUCTION (node $h$) returns $u(h)$} \\ \mbox{if $h \in Z$ then} \\ \mbox{lem: certain $L$ return $u(h)$} \\ \mbox{best\_util} \leftarrow -\infty \\ \mbox{forall $a \in \chi(h)$ do} \\ \mbox{lem: certain $d \leftarrow BACKWARDINDUCTION(\sigma(h, a))$} \\ \mbox{if $util\_at\_child \leftarrow BACKWARDINDUCTION(\sigma(h, a))$} \\ \mbox{if $util\_at\_child \leftarrow best\_util_{\rho(h)} > best\_util_{\rho(h)}$} \\ \mbox{then $L$ best\_util \leftarrow util\_at\_child$} \\ \mbox{return $best\_util$} \end{array}
```

- $util_at_child$ is a vector denoting the utility for each player
- the procedure doesn't return an equilibrium strategy, but rather labels each node with a vector of real numbers.
 - This labeling can be seen as an extension of the game's utility function to the non-terminal nodes
 - Equilibrium strategies take a best action at each node.

Game Theory Course: Jackson, Leyton-Brown & Shoham

Computing Subgame Perfect Equilibria

Idea: Identify the equilibria in the bottom-most trees, and adopt

these as one moves up the tree

```
\begin{array}{l} \mbox{function BACKWARDINDUCTION (node $h$) returns $u(h)$} \\ \mbox{if $h \in Z$ then} \\ \mbox{lem: constraint $L$ return $u(h)$} \\ \mbox{best\_util} \leftarrow -\infty \\ \mbox{forall $a \in \chi(h)$ do} \\ \mbox{lem: child $\leftarrow$ BACKWARDINDUCTION($\sigma(h, a)$)$} \\ \mbox{if $util\_at\_child $\leftarrow$ BACKWARDINDUCTION($\sigma(h, a)$)$} \\ \mbox{if $util\_at\_child$} \leftarrow \mbox{util\_at\_child$} \\ \mbox{L best\_util $\leftarrow$ util\_at\_child$} \\ \mbox{return $best\_util$} \end{array}
```

- For zero-sum games, BackwardInduction has another name: the minimax algorithm.
 - Here it's enough to store one number per node.
 - It's possible to speed things up by pruning nodes that will never be reached in play: "alpha-beta pruning".

Centipede Game

- What happens when we use this procedure on Centipede?
 - In the only equilibrium, player I goes down in the first move.
 - This outcome is Pareto-dominated by all but one other outcome.
- Two considerations:
 - practical: human subjects don't go down right away
 - theoretical: what should player 2 do if player 1 doesn't go down?
 - SPE analysis says to go down. However, that same analysis says that PI would already have gone down. How should player 2 update beliefs upon observation of a measure zero event?
 - but if player 1 knows that player 2 will do something else, it is rational for him not to go down anymore... a paradox
 - there's a whole literature on this question
